

Vibration, Audio, Back Button And Pop-Under Scripts (Updated)

I have included and updated version of these scripts within a basic landing page. I have provided instructions below on how to extract and implement the scripts below.

You can see these scripts in action on your MOBILE device by visiting <http://cashmoneyaffiliate.com/scripts240816/>

DOWNLAOD

Vibration script => index.html => lines from 74 to 77 => you can simply delete it to disable

The best location in HTML would be at the bottom, right before the closing body tag (</body>)

*for desktop this script does NOT function (it is simply disabled)

Back button script => index.html

first, you need to include file “backfix.min.js” just like on line 9 – this is a micro framework that fixes some browsers issues right after including the back fix, the script is on lines from 10 to 17 (index.html)

line 11 is the link for redirection on back button clicked on line 13 – you have a command that disables exit pop before redirecting to back button link – if you don’t want it, just delete this line of code.

Audio

- the audio element is between lines 20 and 24
- the element must have an ID (in this case – audio)
- on first line there is autoplay option enabled (works only on desktop devices, not on mobile) – if you don't want it just delete this “autoplay”
- there are 3 types of audio files (you have free online converters to achieve these 3 types) that all of the devices support. When a device loads this element, it chooses only one type that it supports (usually the first one), while the other 2 is not loaded.
- the audio element should be placed right after opening body tag (<body>)
- right after it, there is a script for closing custom entry alert (alert must be custom, not generic) , and triggering play on the audio element. (this works on mobile, as well as on desktop) – lines 26 to 33 – this script needs jquery included in order to work
- right after it I have included a custom alert with absolute centering just for demonstration purpose (using CSS)
- to disable audio delete both the audio element and the script for audio

Popunder Script

index.html => lines from 61 to 70

This is just one of thousands of variations for creating a pop-under. These scripts are usually created according to the needs of the page. Things get much harder when it needs to be created with page progress (something on the page has already been clicked) – this kind of scripts can have up to 100 lines of code.

So, this is just a simple one that works only when the page has nothing dynamic on it, this script needs jquery to work.
